- windows version 2019 was successfully installed on all workstations and tested, serial keygen - windows version 2019 are on an ongoing basis) as well as test changes to the messages sent to and received from a virtual machine on remote Azure services. I am confident that the solution can be implemented using some form of triggers or services. I have created both a trigger and a service in Azure which send a message to the service bus queue when a queue message is received (in case there is something to be done). What I am not able to figure out is how to retrieve the Message in the triggered function. For a normal Azure function, we can get the data using the context, however this is a service function and not a VM. When I use the context.Caller.ToString(), it shows that it is the remote VM itself (not the function code). When I use.Data, it is an empty array. Any ideas? A: You can use the channel.Context.SetEventGridEventData method to set the event data as the Message Object with the function body, The code is below. serviceBusTrigger.Messages.ProcessMessageBodyAsync("hostfunctionpath",.)=> { var functionCaller= message.Body.Caller; var message = System.Text.Encoding.UTF8.GetString(message.Body.Data); var msg = new Message("log4inet") { Body = new { id = 1, test = "10" }, Subject = functionCaller.ToString() + " - EventData - " + DateTime.Now.ToString() }; 82157476af
